

Internal AI - Software Engineer Challenge

Problem

You are building a tool for a book publishing company.

The editorial team needs to review and analyze books efficiently. This includes:

- exploring and understanding book content
- answering questions about specific parts of a book
- identifying relevant passages
- comparing content across books (e.g., when reviewing potential similarities between authors' work)

The goal is to support editors in making informed decisions, based on relevant and well-grounded information.

Overview

Build a lightweight full-stack application that allows users to explore a small collection of books and interact with an AI assistant.

The assistant should help users understand and work with the content of the books, for example, answering questions, retrieving relevant information, analyzing text, or comparing content across books.

You will be provided with:

- Access to LLM and embedding models
- A dataset containing 2 books (full text)

The goal of this challenge is to evaluate how you design and build an AI powered system, including how you structure the problem, orchestrate LLMs and data sources, manage context and reasoning and make pragmatic technical decisions.

Expectations

Your solution should include:

- A minimal interface to interact with the system (UI, CLI, or API)
- An AI assistant capable of handling natural language requests about the books
- A system that can retrieve and use relevant information from the dataset to support its responses

Some use cases may require working across multiple documents (e.g., identifying similar passages and supporting conclusions with evidence).

Beyond this, you are free to design the system as you see fit.

Technical Expectations

- Backend: Python or Node.js
- Frontend: React or Vue.js
- The solution should run locally
- Docker is preferred

Deliverables

- Project code in a `.zip` file
- `README.md` with:
 - setup instructions
 - explanation of the approach
 - key technical decisions, assumptions, and trade-offs

We expect most candidates to spend around 4–6 hours using AI tools.
